#### Lecture 4 - Consumer Choice

ECON 3070 - Intermediate Microeconomic Theory

Michael R. Karas

January X, 2025

#### Overview

In the previous lecture, we looked at consumer preferences.

- We considered how consumers ranked various bundles of goods.
- We saw how to graphically and numerically represent these preferences.

In the next lecture, we will consider how consumers choose which bundle to consume.

#### The Budget Constraint

Consumers only have a limited amount of money to spend on goods and services.

 A consumer's budget constraint defines the set of baskets that a consumer can purchase.

## The Budget Constraint

Consumers only have a limited amount of money to spend on goods and services.

- A consumer's budget constraint defines the set of baskets that a consumer can purchase.
- If  $P_x$  is the price of good x, then  $P_x x$  is the amount of money spent on good x
- Similarly,  $P_y y$  is the amount of money spent on good y.

## The Budget Constraint

Consumers only have a limited amount of money to spend on goods and services.

- A consumer's budget constraint defines the set of baskets that a consumer can purchase.
- If  $P_x$  is the price of good x, then  $P_x x$  is the amount of money spent on good x
- Similarly,  $P_y y$  is the amount of money spent on good y.

Because a consumer can only spend as much as their income, I, their budget constraint can be expressed as:

$$P_x x + P_y y \le I$$

# **Budget Constraint**

The budget constraint can be generalized to more than two goods:

$$P_{x_1}x_1 + P_{x_2}x_2 + \dots + P_{x_n}x_n \le I$$

- Because more is better (remember our assumptions), the consumer will always use up their whole budget (I).
- In general, however, a consumer can purchase any bundle which costs I\$ or less.

A consumer's budget constraint for two goods can also be represented graphically. In the equation  $P_x x + P_y y = I$ , solve for y.

A consumer's budget constraint for two goods can also be represented graphically. In the equation  $P_x x + P_y y = I$ , solve for y.

The rearranged equation is

$$y = \frac{I}{P_y} - \frac{P_x}{P_y}x$$

 This equation in slope-intercept form can be used to plot our budget line.

A **budget line** shows all combinations of goods x and y that can be purchased for a given budget I, at given prices  $P_x$  and  $P_y$ .

#### Try It Yourself

Write the budget constraint with I=800,  $P_X=20$ , and  $P_Y=40$ . Then, solve for y.

Figure: The Budget Line

The y intercept tells us how many units of good y can be purchased if none of good x is bought. Similarly for the x intercept.

The y intercept tells us how many units of good y can be purchased if none of good x is bought. Similarly for the x intercept.

The slope tells us how many units of good y must be given up to obtain one more unit of good x.

The y intercept tells us how many units of good y can be purchased if none of good x is bought. Similarly for the x intercept.

The slope tells us how many units of good y must be given up to obtain one more unit of good x.

#### Conceptual questions

- Remember that a change in income shifts the budget line, without changing the slope (why?)
- What would a change in the price of one (or both) of the goods do?

#### Try It Yourself

Suppose that Sammy has \$200 in disposable income to spend each month on concert tickets and football tickets. Concert tickets cost \$50 and football tickets cost \$20. The price of concert tickets increases by \$25, and the price of football tickets increases by \$10. Assume that Sammy's disposable income doesn't change.

Draw the budget line before and after.

# Optimal Choice

Now that we know the consumer's problem (maximize utility), and their constraint (the budget constraint), we can determine the consumer's optimal choice.

- The optimal choice is the amount of each good that should be purchased in order to maximize utility.
- This basket of goods must be located on the budget line (why not below?).

### Optimal Choice

More formally, we can state the consumer's **utility maximization** problem as:

$$\max_{(x,y)} U(x,y)$$
 subject to:  $P_x x + P_y y \leq I$ 

## **Utility Maximization**

How can we interpret this graphically?

- Remember that the consumer wants to get to the highest indifference curve possible.
- That means moving as far up and to the right as possible
- But the consumer can't move beyond their budget line.

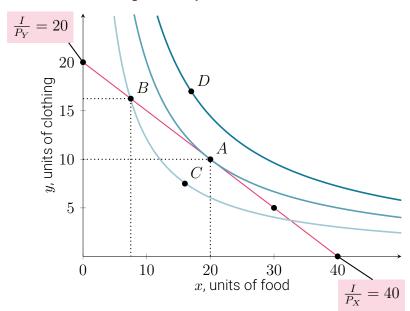

# **Utility Maximization**

How can we interpret this graphically?

- Remember that the consumer wants to get to the highest indifference curve possible.
- That means moving as far up and to the right as possible
- But the consumer can't move beyond their budget line.

The optimal bundle ends up being (in most cases) the point where the budget line is tangent with one of the indifference curves.

#### Figure: Utility Maximization

### **Utility Maximization**

To find the consumer's optimal level of consumption of x and y, we need some calculus.

We will maximize utility in two-ways:

- 1. The method of Lagrange
- 2. 'plugging-in' the constraint to our problem.

Define the Lagrangian  $(\mathcal{L})$  as

$$\mathcal{L}(x, y, \lambda) = U(x, y) + \lambda (I - P_x x - P_y y)$$

Maximizing the Lagrangian with respect to x,y, and  $\lambda$  is equivalent to maximizing the original problem.

Define the Lagrangian  $(\mathcal{L})$  as

$$\mathcal{L}(x, y, \lambda) = U(x, y) + \lambda (I - P_x x - P_y y)$$

To maximize the Lagrangian, take derivatives with respect to x, y, and  $\lambda$ , and set them equal to zero. The first order conditions for an optimum are:

$$\frac{\delta \mathcal{L}}{\delta x} = 0 \Rightarrow \frac{\delta U(x, y)}{\delta x} = \lambda P_x$$

$$\frac{\delta \mathcal{L}}{\delta y} = 0 \Rightarrow \frac{\delta U(x, y)}{\delta y} = \lambda P_y$$

$$\frac{\delta \mathcal{L}}{\delta \lambda} = 0 \Rightarrow I - P_x x - P_y y = 0$$

Remember that  $\frac{\delta U(x,y)}{\delta x}=MU_x$  and  $\frac{\delta U(x,y)}{\delta y}=MU_y$ . Then, rearranging terms:

$$\frac{MU_x}{P_x} = \lambda$$
 and  $\frac{MU_y}{P_y} = \lambda$ 

Remember that  $\frac{\delta U(x,y)}{\delta x}=MU_x$  and  $\frac{\delta U(x,y)}{\delta y}=MU_y$ . Then, rearranging terms:

$$rac{MU_x}{P_x} = \lambda$$
 and  $rac{MU_y}{P_y} = \lambda$ 

We can combine the first two equations and rearrange terms, and the result is:

$$\frac{MU_x}{P_x} = \frac{MU_y}{P_y}$$

Remember that  $\frac{\delta U(x,y)}{\delta x}=MU_x$  and  $\frac{\delta U(x,y)}{\delta y}=MU_y$ . Then, rearranging terms:

$$rac{MU_x}{P_x} = \lambda$$
 and  $rac{MU_y}{P_y} = \lambda$ 

We can combine the first two equations and rearrange terms, and the result is:

$$\frac{MU_x}{P_x} = \frac{MU_y}{P_y}$$

The resulting equality is our optimality condition.

## Example

Consider U(x,y)=2xy and I=10,  $P_x=2$ ,  $P_y$ . Solve for the Consumers optimal choices of goods x and y using the Lagrangian Method.

#### Try It Yourself

Consider U(x,y)=xy and I=80,  $P_x=4$ ,  $P_y=2$ . Solve for the Consumers optimal choices of goods x and y using the Lagrangian Method.

To solve using unconstrained optimization, first solve for y in the budget constraint  $P_x x + P_y y = I$ .

$$y = \frac{I - P_x x}{P_y}$$

To solve using unconstrained optimization, first solve for y in the budget constraint  $P_x x + P_y y = I$ .

$$y = \frac{I - P_x x}{P_y}$$

We then plug this into our utility function, and our problem becomes:

$$\max_{x} U(x, \frac{I - P_x x}{P_y})$$

To solve using unconstrained optimization, first solve for y in the budget constraint  $P_x x + P_y y = I$ .

$$y = \frac{I - P_x x}{P_y}$$

To solve using unconstrained optimization, first solve for y in the budget constraint  $P_x x + P_y y = I$ .

$$y = \frac{I - P_x x}{P_y}$$

We then plug this into our utility function, and our problem becomes:

$$\max_{x} U(x, \frac{I - P_x x}{P_y})$$

How do we maximize (or minimize) any function?

How do we maximize (or minimize) any function?

• Take derivatives, and set them equal to zero.

Taking the total derivative of  $U(x, \frac{I-P_xx}{P_y})$  w.r.t x (using the chain-rule!):

$$\frac{dU}{dx} = \frac{\delta U}{\delta x} + \frac{\delta U}{\delta y} \frac{dy}{dx} = 0$$

$$\Rightarrow \frac{\delta U}{\delta x} - \frac{\delta U}{\delta y} \frac{P_x}{P_y} = 0$$

$$\Rightarrow \frac{\delta U}{\delta x} / P_x = \frac{\delta U}{\delta y} / P_y$$

$$\Rightarrow \frac{MU_x}{P_x} = \frac{MU_y}{P_y}$$

# Example

Consider U(x,y)=2xy and I=10,  $P_x=2$ ,  $P_y$ . Solve for the Consumers optimal choices of goods x and y using Unconstrained Optimization.

#### Try It Yourself

Consider U(x,y)=xy and I=80,  $P_x=4$ ,  $P_y=2$ . Solve for the Consumers optimal choices of goods x and y using Unconstrained Optimization.

# The Optimality Condition

We have just found our first optimality condition! Now that we have derived this from first principles, we don't have to do that again!

$$\frac{MU_x}{P_x} = \frac{MU_y}{P_y}$$

We have just found our first optimality condition! Now that we have derived this from first principles, we don't have to do that again!

$$\frac{MU_x}{P_x} = \frac{MU_y}{P_y}$$

- The optimality condition tells us that the consumer maximizes utility when the marginal utility per dollar spent on both goods is equal.
- Think about what would happen if it weren't equal for the two goods.

We can also rearrange the optimality condition as follows:

$$\frac{MU_x}{MU_y} = \frac{P_x}{P_y}$$

 This tells us that the slope of our indifference curve should equal the slope of our budget line.

We can also rearrange the optimality condition as follows:

$$\frac{MU_x}{MU_y} = \frac{P_x}{P_y}$$

- This tells us that the slope of our indifference curve should equal the slope of our budget line.
- The result is that the optimal basket is located where the budget line is exactly tangent to one of the indifference curves.
- Compare this to our graphical result.

So far, we only considered the case where baskets contain two goods. However, the optimality condition holds for any number of goods.

$$\frac{MU_{x_1}}{P_{x_1}} = \frac{MU_{x_2}}{P_{x_2}} = \dots = \frac{MU_{x_n}}{P_{x_n}}$$

 As before, the utility per dollar spent on each good (or "bang for your buck"), must be equal.

So far, we only considered the case where baskets contain two goods. However, the optimality condition holds for any number of goods.

$$\frac{MU_{x_1}}{P_{x_1}} = \frac{MU_{x_2}}{P_{x_2}} = \dots = \frac{MU_{x_n}}{P_{x_n}}$$

 As before, the utility per dollar spent on each good (or "bang for your buck"), must be equal.

This is a *key insight*! This optimality condition is how we think individuals balance trade-offs on what to buy

### Try It Yourself

Consider a market with only two goods, bread and cheese. Suppose that at Francis' current level of consumption, his marginal utility of bread is 4, and is marginal utility of cheese is 6. Suppose that a loaf of bread costs \$3, and a pound of cheese costs \$6. What should Francis do?

Now that we know something about the optimal bundle (from the optimality condition), how do we actually find it?

- Well we also know that the consumer has only I to spend.
- This gives us a system of two equations (the optimality condition and the budget constraint), and two unknowns (quantity consumed of goods x and y).

Now that we know something about the optimal bundle (from the optimality condition), how do we actually find it?

- Well we also know that the consumer has only \$I to spend.
- This gives us a system of two equations (the optimality condition and the budget constraint), and two unknowns (quantity consumed of goods x and y).

All that's left is some (sometimes messy) algebra.

Suppose  $U(x,y) = x^{\frac{1}{2}}y^{\frac{1}{2}}$ . Let  $P_x = 2, P_y = 3$  and I = 24.

Calculate  $MU_x$  and  $MU_y$  and the optimality condition

Suppose  $U(x,y) = x^{\frac{1}{2}}y^{\frac{1}{2}}$ . Let  $P_x = 2, P_y = 3$  and I = 24.

$$MU_x = rac{y^{rac{1}{2}}}{2x^{rac{1}{2}}}$$
 and  $MU_y = rac{x^{rac{1}{2}}}{2y^{rac{1}{2}}}$ 

Then our optimality condition is  $\frac{y^{\frac{1}{2}}}{2x^{\frac{1}{2}}}/\frac{x^{\frac{1}{2}}}{2y^{\frac{1}{2}}}=\frac{2}{3}$ 

$$\implies y = \frac{2}{3}x$$

Plugging the optimality condition into our budget constraint

$$2x + 3y = 24 \implies 2x + 3(\frac{2}{3}x) = 24 \implies x^* = 6$$

Suppose  $U(x,y) = x^{\frac{1}{2}}y^{\frac{1}{2}}$ . Let  $P_x = 2, P_y = 3$  and I = 24.

$$MU_x = \frac{y^{\frac{1}{2}}}{2x^{\frac{1}{2}}}$$
 and  $MU_y = \frac{x^{\frac{1}{2}}}{2y^{\frac{1}{2}}}$ 

Then our optimality condition is  $\frac{y^{\frac{1}{2}}}{2x^{\frac{1}{2}}}/\frac{x^{\frac{1}{2}}}{2y^{\frac{1}{2}}}=\frac{2}{3}$ 

$$\implies y = \frac{2}{3}x$$

Plugging the optimality condition into our budget constraint

$$2x + 3y = 24 \implies 2x + 3(\frac{2}{3}x) = 24 \implies x^* = 6$$

Plugging  $x^*$  back into the optimality condition,  $y^* = \frac{2}{3}6 = 4$ 

We could also leave out prices and income, and simply solve for x and y in terms of  $P_x$ ,  $P_y$ , and I.

Take the rearranged optimality condition  $y=x\frac{P_x}{P_y}.$  Plug into budget constraint

$$P_x x + P_y x(\frac{P_x}{P_y}) = I \implies x^* = \frac{I}{2P_x}$$

Plug *x* back into the optimality condition:

$$y^* = \frac{I}{2P_x} \frac{P_x}{P_y} = \frac{I}{2P_y}$$

#### **Demand Functions**

The resulting **demand functions** are:

$$x^*(P_x, P_y, I) = \frac{I}{2P_x}$$
 and  $y^*(P_x, P_y, I) = \frac{I}{2P_y}$ 

#### **Demand Functions**

The resulting **demand functions** are:

$$x^*(P_x, P_y, I) = \frac{I}{2P_x}$$
 and  $y^*(P_x, P_y, I) = \frac{I}{2P_y}$ 

The **demand function** is useful since we do the work once and then can predict what that person will consumer under any  $(P_x, P_y, I)$  combination for comparative statics

I'll likely do this on the test

#### Try It Yourself

Consider  $U(x,y)=x^{\frac{1}{2}}y^{\frac{1}{2}}$  and I=80,  $P_x=4$ ,  $P_y=2$ . Solve for the Consumers optimal choices of goods x and y and the resulting demand functions.

### Three Utility Functions

How do you find demand for the three utility functions?

1. Cobb-Douglas:  $U(x,y) = x^{\alpha}y^{\beta}$ 

2. Perfect Substitutes: U(x,y) = ax + by

3. Perfect Complements:  $U(x,y) = \min(ax,by)$ 

### Cobb-Douglas

 $U(x,y) = x^{\alpha}y^{\beta}$ . Our optimality condition is

$$\frac{MU_x}{P_x} = \frac{MU_a}{P_y} \implies \frac{\alpha x^{\alpha - 1} y^{\beta}}{P_x} = \frac{\beta x^{\alpha} y^{\beta - 1}}{P_y} \implies x = \frac{\alpha P_y}{\beta P_x} y$$

Our budget constraint is

$$I = P_x x + P_y y$$

Solve these two equations for  $x^*$  and  $y^*$ .

#### Try It Yourself

Consider  $U(x,y)=x^{\frac{1}{4}}y^{\frac{3}{4}}$  and I=400,  $P_x=20$ ,  $P_y=40$ . Solve for the Consumers optimal choices of goods x and y and the resulting demand functions.

$$U(x,y) = ax + by$$
. Our optimality condition is

$$\frac{MU_x}{P_x} = \frac{MU_a}{P_y} \implies \frac{a}{P_x} = \frac{b}{P_y}$$

U(x,y) = ax + by. Our optimality condition is

$$\frac{MU_x}{P_x} = \frac{MU_a}{P_y} \implies \frac{a}{P_x} = \frac{b}{P_y}$$

Wait! This isn't always true!!

• e.g. what if U(x,y)=x+y,  $P_x=1$ , and  $P_y=2$ . This says 1=1/2 which isn't true

U(x,y) = ax + by. Our optimality condition is

$$\frac{MU_x}{P_x} = \frac{MU_a}{P_y} \implies \frac{a}{P_x} = \frac{b}{P_y}$$

Wait! This isn't always true!!

• e.g. what if U(x,y)=x+y,  $P_x=1$ , and  $P_y=2$ . This says 1=1/2 which isn't true

Since both goods are perfectly substitutable, you should consume **ONLY** the good that provides marginal utility per dollar (bang for your buck)

U(x,y) = ax + by. For perfect substitutes our demand rule is simple:

1. If  $MU_x/P_x > MU_y/P_y$ :

$$x^* = I/P_x \quad \text{ and } \quad y^* = 0$$

2. If  $MU_x/P_x < MU_y/P_y$ :

$$x^* = 0$$
 and  $y^* = I/P_y$ 

3. If  $MU_x/P_x = MU_y/P_y$ :

#### Corner Solutions

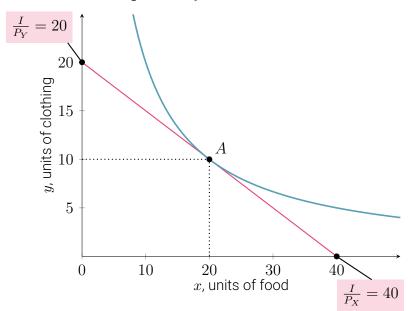

So far are our maximization problems have had interior solutions where positive quantities of both goods are consumed, e.g.

$$x^* > 0 \& y^* > 0$$

Key characteristic is that the optimal solution is where the indifference curve is tangent to the budget constraint, which requires preferences to be "well-behaved":

- Smooth
- Convex (curved in)
- Not touch the two axis

#### Figure: Utility Maximization

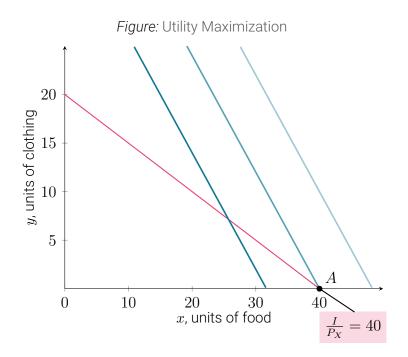

#### Corner Solutions

At a corner solution only one good is consumed at a positive quantity, e.g.  $x^*>0$  &  $y^*=0$ 

Occurs when preferences are not well-behaved, such as by crossing one of the axis

Optimal solution is to spend all income on one good and none on the other good

#### Try It Yourself

Consider U(x,y) = xy + 7y and I = 10,  $P_x = 1$ ,  $P_y = 2$ . Solve for the Consumers optimal choices of goods x and y and the resulting demand functions.

### Perfect Complements

 $U(x,y) = \min(ax,by)$ . How do we even take a derivative of this?

### Perfect Complements

 $U(x,y) = \min(ax,by)$ . How do we even take a derivative of this?

Instead, recognize that perfect complements means you have to consume always in the proportion ax = by.

• If ax > by, you are wasting money on x and vice-versa if by > ax

### Perfect Complements

 $U(x,y) = \min(ax,by)$ . How do we even take a derivative of this?

Instead, recognize that perfect complements means you have to consume always in the proportion ax = by.

• If ax > by, you are wasting money on x and vice-versa if by > ax

ax = by is therefore our optimality condition! Our budget constraint is

$$I = P_x x + P_y y$$

Solve these two equations for  $x^*$  and  $y^*$ .
